

Clarification on the Calculation of Performance Measurement for the Assignment on Template Matching

While calculating the number of times the reference template is searched in the target frame, **ignore the variation of the template dimension** in successive decomposition levels in case of **hierarchical method**. It is **not required** to normalize the count due to the reduction of the template size in higher decomposition levels.

In summary, **count** the numbers of times the reference object is searched in different frames, and **average** them over the entire video sequence. This is **to be repeated** for every selection of p .
